

The 9p21 locus read per tumour

Filled circles are EMC tumours, open squares comparator sarcomas; bars in the left panel are medians, while the manuscript table reports differences of means, so the two need not agree in direction for a gene as flat as MTAP. Right: a homozygous 9p21 deletion removes MTAP and CDKN2A together, so a deleted tumour would fall in the lower-left quadrant. Five EMC tumours sit below every comparator for MTAP and all five carry CDKN2A above their array median, which is the opposite of the co-deletion pattern. No tumour on either platform falls in that quadrant.
