

## Transcriptome load per junction gapmer against chance expectation

176 distinct oligonucleotides at real exon junctions, ranked; exact plus  $\leq 1$ -mismatch matches over 186,185 transcripts.

◆ the 9 designs spanning two or three partners' seams, each one molecule plotted once. 118 of 176 fall at or below it; the line is what chance alone predicts, not a ceiling.

transcriptome matches at  $\leq 1$  mismatch

The chance expectation assumes independent uniform bases. The line separates "more than chance" from "at chance" and is not a significance test.

Counts are predictions from sequence search, not measured off-target activity. Bars are green at or below the line and red above it, which repeats each bar's own height and carries no information of its own. 58 of the 176 plotted designs sit above it; on the mean the set comes in at chance.

Not plotted: 10 designs at 2 modelled breakpoints rather than real exon junctions; 4 of those sit above it, at 16–95 matches and 75.0–81.2% GC.
