

Cover letter

Dear Editors,

Please consider “Computational design and parent transcript liabilities of NR4A3 fusion junction gapmers in extraskeletal myxoid chondrosarcoma” as a Full-length research article in Computational Biology and Chemistry.

This computational study designs 190 antisense gapmers across 38 modelled NR4A3 fusion junctions and compares conventional near-match screening with contiguous parent-transcript pairing through the catalytic gap. It provides reproducible sequence records, threshold sensitivity and a negative limitation: the strongest exon-terminus control does not resolve a disease-specific excess of parent liability. It reports no laboratory validation or therapeutic window.

The manuscript develops the completed computational results and places proposed model testing in Discussion. Its sequence records, numerical results and original figure remain unchanged from the submitted Qeios version 3 (<https://www.qeios.com/read/VL3LJR.3>). The historical code and analysis archive is <https://doi.org/10.5281/zenodo.22229096>; the accompanying revision note distinguishes that archive from corrected interpretations in the present package.

We request standard subscription publication with online-only color. Optional open access, print color and paid companion-journal publication are not requested.

The submitted author-interest, funding and AI disclosures are retained in the manuscript. Final personal author declarations and journal submission remain for the author to complete.

Sincerely,

Tristan D. McRae
