

Transcriptome load per junction gapmer against chance expectation

70 designs, ranked; exact plus ≤ 1 -mismatch matches over 186,185 transcripts. 55 of 70 fall at or below the chance upper bound.

Chance band assumes independent uniform bases over an assumed transcriptome span; it separates "more than chance" from "at chance" and is not a significance test. Counts are predictions from sequence search, not measured off-target activity. The red designs are GC-rich, low-complexity sequences at one modelled seam.
